Duct Sealing and Testing

2015 IECC (w/ Amendments) Inspection Guide

Duct Testing and Sealing:

Summary: New to Virginia with the 2015 Code Cycle is Mandatory testing of ducts, requiring 4% Duct Leakage based on Conditioned Floor Area (CFA) or less. This guide is intended to give both code and real world examples of what that change means for code enforcement in the Commonwealth.

Why: Consistent enforcement of the 2015 Duct Leakage provisions within the code will save the occupants of the roughly 20,000 new homes built each year a combined \$1.24 Million on an annual basis. (Figure 1).¹ According to the Building America Solutions Center, "Duct leakage is a double hit on the utility bill: 1) duct leaks are an uncontrolled loss of conditioned air to the outdoors and 2) duct leakage drives building infiltration. For example, if a home had a 2.5-ton (30,000 BTU/H) cooling system moving 1,000 CFM (cubic feet per minute) of air and the ducts had 10% leakage (which is typical in codebuilt homes), the leakage rate would be 100 CFM. Each cubic foot of air carries with it 30 BTUs/H, so 3,000 BTUs of conditioned air would be lost to the outdoors each hour."² In addition to monetary and energy concerns, uncontrolled infiltration can have large health and durability impacts.

Measure	Total Energy	Total Energy Cost	Total State Emissions Reduction
	Savings (MMBtu)	Savings (\$)	(MT CO2e)
Duct Leakage	6,4168	1,244,243	31,520

Figure 1: Estimated Annual Statewide Savings Potential

If any component of an HVAC System is located outside of the building's thermal envelope, the system will be required to be pressure tested to determine air leakage. This test can take place at Rough-In or after HVAC Trim Out has been completed. There are differing standards for leakage based on what components are installed during the time of the test.

- 3 Cubic Feet per Minute (CFM) / 100 Sq. Ft. of Floor Area Served (or 3% of CFA at rough-in without the air handler installed
- 4 Cubic Feet per Minute (CFM) / 100 Sq. Ft. of Floor Area Served (or 4% of CFA at rough-in with the air handler installed or at final)

Duct Leakage = $\frac{cfm_{25}}{square ft. of floor area served (CFA)}$

² <u>https://basc.pnnl.gov/resource-guides/sealed-and-insulated-flex-ducts#edit-group-description</u>

Anyone that has been substantially trained on the duct testing equipment is able to perform duct leakage testing per Virginia Code.

Determining the necessity of Duct Testing

- 1. Determine Location of HVAC Systems within the home:
 - a. Are all Ducts located within a Crawl Space/Attic/Between Floor/Dropped Ceiling?
 - i. If 'Yes'
 - 1. Do drawings indicate these locations to be within the Building's Thermal Envelope (Section R403.3.7)
 - 2. If Yes No Testing Required
 - ii. If 'No'
 - 1. Duct testing is required
- 2. If duct testing is required, the square feet each system being installed is serving must be determined in order to understand necessary duct leakage targets.
 - a. Ex) 1 system serving the entire home. Conditioned floor area of the home is 1,200 sq. ft.

4% of conditioned floor area = **1,200 X 0.4 = 48**

To pass final duct leakage at final inspection: CFM_{25} must be ≤ 48 CFM

A written report of the results of the test shall be signed by the party conducting the test and provided to the Code Official. Check to ensure all systems are at or below required duct leakage based on floor area served.

Notes:

- * Duct boot to drywall and duct boot to subfloor connections are typically the largest offenders for total leakage, including returns boot connections to drywall
- * Duct boots can be easily covered by drywall and lead to higher leakage in the field
- * Ventilation systems connected to the central Heating and Cooling system can also increase leakage if not operating properly
- * Based on the <u>Virginia Residential Energy Code Field Study</u> results, 94% of systems tested were over the upcoming 4 cfm/100 sq ft threshold, with that dropping to an 84% failure rate with the conditioned space exemption applied
- * Duct leakage drives infiltration, or air leakage, through the envelope; it can negatively or positively pressurize the house depending on where the ducts are leaking, pulling outside air in through cracks in the building envelope or pushing conditioned air out. If the duct leakage is in the supply-side ducts, the house will be negatively pressurized compared to outdoors. If all the leakage is on the return side, the building will be positive with respect to outdoors³

Duct Testing Code Reference:

Section R403.3.3/N1103.3.3 Duct testing (mandatory). Ducts shall be pressure tested to determine air leakage by one of the following methods:

- 1. **Rough-in test**. Total leakage shall be measured with a pressure differential of 0.1 inch water gage (25 Pa) across the system, including the manufacturer's air handler enclosure if installed at the time of the test. All registers shall be taped or otherwise sealed during the test.
- Post-construction test. Total leakage shall be measured with a pressure differential of 0.1 inch water gage (25 Pa) across the entire system, including the manufacturer's air handler enclosure. Registers shall be taped or otherwise sealed during the test.

Exception:

A duct air leakage test shall not be required where the ducts and air handlers are located entirely within the *building thermal envelope*.

A written report of the results of the test shall be signed by the party conducting the test and provided to the code official. The licensed mechanical contractor installing the mechanical system shall be permitted to perform the duct testing. The contractor shall have been trained on the equipment used to perform the test.

Section R403.3.4/N1103.3.4 Duct Leakage (Prescriptive). The total leakage of the ducts, measured in accordance with Section R403.3.3/N1103.3.3, shall be as follows:

- Rough-in test. The total leakage shall be less than or equal to 4 cubic feet per minute (113.3 L/min) per 100 square feet (9.29 m2) of conditioned floor area where the air handler is installed at the time of the test. Where the air handler is not installed at the time of the test, the total leakage shall be less than or equal to 3 cubic feet per minute (85 L/min) per 100 square feet (9.29 m2) of conditioned floor area.
- 2. **Post-Construction test.** Total leakage shall be less than or equal to 4 cubic feet per minute (113.3 L/min) per 100 square feet (9.29 m2) of conditioned floor area.

Duct Sealing Code Reference:

Section R403.3.2/N1103.3.2 Sealing (Mandatory). Ducts, air handlers and filter boxes shall be sealed. Joints and seams shall comply with the International Mechanical Code or International Residential Code where applicable.

Exceptions:

1. Air-impermeable spray foam products shall be permitted to be applied without additional joint seals.

For ducts having a static pressure classification of less than 2 inches of water column (500 Pa), additional closure systems shall not be required for continuously welded joints and seams, and locking-type joints and seams of other than the snap-lock and button-lock types.

Section R403.3.2.1/N1103.3.2.1 Sealed Air Handler. Air handlers shall have a manufacturer's designation for an air leakage of no more than 2 percent of the design air flow rate when tested in accordance with ASHRAE 193

Duct Location Code Reference:

Section R403.3.5/N1103.3.5 Building Cavities (mandatory). Building framing cavities should not be used as ducts or plenums.

Definitions:

Building Thermal Envelope: The basement walls, exterior walls, floor, roof and any other building elements that enclose conditioned space or provide a boundary between conditioned space and exempt or unconditioned space

Conditioned Space: An area, room or space that is enclosed within the building thermal envelope and that is directly heated or cooled or indirectly heated or cooled

Above-Grade Wall: A wall more than 50% above grade and enclosing conditioned space. This includes between-floor spandrels, peripheral edges of floors, roof and basement knee-walls, dormer walls, gable end walls, walls enclosing mansard roof and skylight shafts

Air Barrier: Material(s) assembled and joined together to provide a barrier to air leakage through the building envelope. An air barrier may be a single material or a combination of materials

R-Value: Resistance to Heat Flow of a single material, expressed as a whole number. Higher numbers denote higher resistance to heat flow

U-Value: Resistance to heat flow of multiple materials expressed as a decimal point. Lower numbers denote higher resistance to heat flow

Infiltration: The uncontrolled inward air leakage into a building caused by the pressure effects of wind, or the effect of differences in the indoor and outdoor air density or both
